

Asia/World Energy Outlook 2009

—The Role of Technology Towards the Resolution of
Energy & Environmental Issues in Asia—

The Institute of Energy Economics, Japan (IEEJ)

[Summary]

This report analyzes energy demand and supply in the world and in Asia over the long term through 2035, based on new trends in the world economy, including the economic development of emerging countries mainly in Asia, as well as changes in the international energy situation and technology trends. Currently, the role of low-carbon technology is expected to expand even further in tackling global warming issues and securing stable energy supply. Thus, in addition to the “reference scenario” which considers past trends and incorporates current energy and environment policies, the report provides “technologically advanced scenario” where advanced low-carbon technology becomes even more widespread around the world on the back of the promotion of international technology transfers.

[Main conclusions]

In the future, in Asian developing countries, including China and India, demand for fossil fuel such as oil will expand sharply reflecting on its strong economic growth, their dependence on oil imports will rise and CO₂ emissions will increase significantly. Under these circumstances, the best energy mix (efficient use of fossil fuels and diversification of energy sources), the securing of oil and gas resources, and the enhancement of measures against global warming through technology transfers will become important issues in Asia. It will be important for Japan to cooperate toward achieving sustainable economic growth in Asian countries, and at the same time contribute to tackling global warming issues and resolving energy security problems through transfers of Japan’s sophisticated energy conservation and environmental technology to Asian countries.

- The world’s primary energy consumption (reference scenario) will expand from 11.1 billion tons oil equivalent (Btoe) in 2007 to 16.9 Btoe in 2035. Fossil fuels will account for 79% of the primary energy consumption growth during this period, continuing to serve as an important major energy source.
- Global CO₂ emissions (reference scenario) will increase from 28.8 billion tons in 2007 to 33.9 billion tons in 2020 (up 60% from 1990 levels) and 41.5 billion tons in 2035 (up 96% from 1990 levels). In 2020, which is a key period in the framework of post-Kyoto Protocol

negotiations, CO₂ emissions will increase by 300 million tons from 2007 in developed countries (up 19% from 1990 levels), while increasing by 4.9 billion tons in developing countries (up 108% from 1990 levels and 16 times the increase of developed countries). Thus, there is an urgent need to strengthen measures to reduce emissions in developing countries.

- If low-carbon technology becomes even more widespread in countries around the world, global CO₂ emissions will peak out in 2026 and Asia's CO₂ emissions will peak in 2030.
- With regard to China, if advanced technology is introduced through the promotion of technology transfers, primary energy consumption will peak out in 2033, while CO₂ emissions will peak in 2030 if Carbon Capture and Storage (CCS) technology is not considered and in 2025 if they are considered.
- Due to the expansion of low-carbon technology, the world's CO₂ emissions in 2035 will be 12.3 billion tons (or 30%) less than in the reference scenario (The reduction is equivalent to approximately 10 times as much as Japan's emissions.) Of the 12.3-billion-ton CO₂ reduction, developed countries will be responsible for 4.2 billion tons and developing countries 8.1 billion tons. Thus, the CO₂ emissions reduction in developing countries will be nearly double that of developed countries. Asia's CO₂ emissions reduction will reach 6.8 billion tons, accounting for approximately 60% of the world's total reduction, indicating Asia's extremely high CO₂ reduction potential. It will thus be important to provide technology transfers and technology cooperation to the Asian region.
- Energy conservation, nuclear power, renewable energy, fuel switching and CCS will play a central role in realizing low-carbon energy system. Of the world's CO₂ reduction of 12.3 billion tons in 2035, energy conservation will be responsible for 5.7 billion tons (accounting for 46% of the total reduction), nuclear power 1.3 billion tons (10%), renewable energy 1.2 billion tons (10%), fuel switching 1.5 billion tons (12%) and CCS 2.6 billion tons (21%).

[Major assumptions]

- **Economic growth**

World: While global economic growth has slowed down following the U.S. subprime mortgage crisis, the economic stimulus measures of each country are gradually having an effect and growth will continue in the medium to long term. The world economy will grow at a rate of 2.8% per annum during the period from 2007 to 2035.

Asia: Asia (excluding Japan) will grow at a rate of 4.9% per annum, serving as the locomotive for the world economy. In particular, China and India will grow at respective rates of 5.6% and 6.1%, increasing their presence in the world economy.

- **Population**

The world population will grow from 6.6 billion in 2007 to 8.5 billion in 2035. Within Asia, the population will expand to 1.46 billion in China and 1.53 billion in India by 2035. The population of the entire Asian region will increase to 4.5 billion, accounting for 53% of the world total.

- **Crude oil price**

The crude oil price (the Japanese import price on a C.I.F. basis and the real price based on the currency value in 2008), which stood at \$103/barrel in 2008, will come to \$95/barrel in 2020, \$109/barrel in 2030 and \$117/barrel in 2035. (Crude oil prices are predicted in ranges, and are estimated to move in the range of around \$90/barrel to \$110/barrel in 2020 and around \$110/barrel to \$130/barrel in 2035. A roughly intermediate value of the range is used for the assumption of the model analysis.)

- **Scenario**

The “reference scenario,” which serves as the basis of analysis, is based on probable policies and technology developments. The “technologically advanced scenario” assumes major global progress in technology development and the spread of innovative technology in response to strengthened energy security and measures against global warming.

[Major results] (Reference Scenario)

- **World**

Primary energy consumption

The world's primary energy consumption is expected to grow at a rate of 1.5% per annum, from 11.1 billion tons oil equivalent in 2007 to 16.9 Btce in 2035. The share of fossil fuels, which is at 89% in 2007, will move to 86% in 2035. Fossil fuels will account for 79% of the primary energy consumption growth up to 2035, remaining a major energy source in the future.

Global oil demand will increase by 28 million barrels per day (at a rate of 1.0% per annum), from 85 million b/d in 2007 to 113 million b/d in 2035. However, it will decline at a rate of 0.3% per annum in developed countries (OECD) while rising at a rate of 2.4% per annum in developing countries (Non-OECD). In terms of liquefied natural gas (LNG), world natural gas demand will expand at a rate of 2.1% per annum from 2.0 billion tons in 2007 to 3.6 billion tons in 2035. Global coal demand will grow at a rate of 1.2% per annum from 4.6 billion tons coal equivalent (1 tce is equal to 0.7 toe) in 2007 to 6.4 Btce in 2035.

Renewable energy (Photovoltaic power generation, wind power generation, etc.)

The world's photovoltaic power generation capacity will grow sharply from 15 million kilowatts in 2008 to 242 million kilowatts in 2035, a 16-fold increase. The world's wind power generation capacity will expand from 121 million kilowatts in 2008 to 602 million kilowatts in 2035, a five-fold increase. Photovoltaic and wind power generation combined accounted for 0.9% of the world's total

power generation in 2007 and will account for 3.6% in 2035. In addition, the proportion of renewable energy (excluding hydroelectric power) in the world's primary energy consumption will increase from 2.9% in 2007 to 5.4% in 2035.

Nuclear power

The world's nuclear power generation capacity will increase from 392 million kilowatts in 2007 to 602 million kilowatts in 2035. Nuclear power accounted for 14% of the world's total power generation in 2007 and will account for 12% in 2035.

● Asia

Primary energy consumption

Asia's primary energy consumption will grow at a rate of 2.5% per annum, accounting for 61% of the global increase through 2035. Fossil fuels will occupy 82% of Asia's primary energy consumption growth to 2035—33% in coal, 27% in oil and 22% in natural gas. Particularly, Asia will remarkably increase coal consumption, accounting for 90% of the global coal demand increase.

Oil demand and supply

Asia's net oil imports will expand from 730 million tons (15 million b/d) in 2007 to 1.7 billion tons (35 million b/d) in 2035, due to sluggish oil production within the Asian region while oil demand increases based on its progress in industrialization and motorization. Asia's dependence on imports for oil supply will rise from 67% in 2007 to 84% in 2035.

Progress in electrification and electricity supply

As electrification accelerates in Asia along with improvements in income levels and progress in urbanization, electricity consumption will grow 2.5-fold over the next 28 years. Coal-fired power plants backed by abundant coal resources and their economic efficiency will play a central role in meeting the fast electricity consumption growth (dominating 57% of total electricity generation in 2035). Natural gas-fired power plants, which feature higher generation efficiency, will also increase steadily, boosting their share of total electricity generation from 13% in 2007 to 17% in 2035. Asia will increase nuclear power plants rapidly, explaining 137 million kilowatts of the 210 million kilowatts in additional global nuclear power generation capacity to 2035.

Progress in motorization

The number of automobiles owned in Asia will increase from 200 million units in 2007 to 620 million units in 2035 as motorization makes further progress along with rising income levels in Asian developing countries. Despite the spread of innovative automobiles and improvements in fuel efficiency, Asia's oil consumption will double from 22.6 million b/d in 2007 to 42.2 million b/d in 2035.

- **CO₂ emissions**

In parallel with the growth in fossil fuel consumption, global CO₂ emissions will increase from 28.8 billion tons (carbon dioxide equivalent) in 2007 to 33.9 billion tons in 2020 (up 60% from 1990 levels) and 41.5 billion tons in 2035 (up 96% from 1990 levels). Asia's CO₂ emissions will expand by a factor of 1.8, from 10.7 billion tons in 2007 to 19.1 billion tons in 2035. Asia will account for 66% of the total global emissions increase, with China alone accounting for around 30%.

Through 2020, a key period in the framework of post-Kyoto Protocol negotiations, CO₂ emissions will increase by 300 million tons from 2007 in developed countries (up 19% from 1990 levels), while increasing by 4.9 billion tons in developing countries (up 108% from 1990 levels and 16 times the increase of developed countries). Thus, there is an urgent need to strengthen measures to reduce emissions in developing countries.

[Major results] (Technologically Advanced Scenario)

- **Impact of technology development on the world**

In the technologically advanced scenario, innovative technology will become widespread in the world in line with efforts toward securing a stable energy supply, tackling climate change and the promotion of international technology cooperation and international technology transfers. Specifically, this technology will include improved industrial process efficiency, the enhanced energy conservation effects of household appliances, and the expanded introduction of next-generation automobiles, biofuels, clean coal technology, renewable energy, nuclear power and CCS technology.

World: In the technologically advanced scenario, the world's primary energy consumption in 2035 will be 2.3 Btoe (or 14%) less than in the reference scenario. (The energy savings are approximately four times as much as Japan's total energy consumption of 500 million toe.) Of the 2.3 Btoe in energy savings, developed countries will account for 700 million toe and developing countries 1.6 Btoe. Thus, energy savings in developing countries will be more than double those in developed countries. The share of non-fossil energy in world primary energy mix in 2035 will be 21% in the technologically advanced scenario, higher than 15% in the reference scenario.

Asia: Asia's primary energy consumption in 2035 will be 1.3 Btoe (or 19%) less than in the reference scenario. (The energy savings are approximately twice as much as Japan's total energy consumption.) Asia's energy-saving potential is extremely high, with its 1.3 Btoe in energy savings accounting for approximately 60% of the world's energy savings of 2.3 Btoe. The share of non-fossil energy in 2035 will be 19% in the technologically advanced scenario, higher than the 12% in the reference scenario.

- **Impact on CO₂ emissions**

World: The world's CO₂ emissions will increase by 3.4 billion tons (or 13%) between 2005 and 2020 but will peak out in 2026, due to further progress in energy and environmental technology. In 2035, the world's CO₂ emissions will be 12.3 billion tons (or 30%) less than in the reference scenario. (The reduction is equivalent to approximately ten times as much as Japan's emissions.) Of the 12.3-billion-ton CO₂ reduction, developed countries will be responsible for 4.2 billion tons and developing countries 8.1 billion tons. Thus, the CO₂ emissions reduction in developing countries will be nearly double that of developed countries. Asia's CO₂ emissions reduction will reach 6.8 billion tons, accounting for 55% of the world's total reduction, indicating Asia's extremely high CO₂ reduction potential.

Asia: CO₂ emissions in Asia will peak out in 2030 on the basis of technology developments. Asia's CO₂ emissions in 2035 will be 6.8 billion tons (or 36%) less than in the reference scenario. (The reduction is equivalent to approximately six times as much as Japan's emissions.) Of the 6.8-billion-ton CO₂ reduction, China will be responsible for 4.1 billion tons, India 1.5 billion tons and the rest of Asia 1.4 billion tons.

The role of technology: The reduction in CO₂ emissions will be a result of combining various advanced technology, and all options are important. Of the world's CO₂ reduction of 12.3 billion tons in 2035, energy conservation will be responsible for 5.7 billion tons (accounting for 46% of the total reduction), nuclear power 1.3 billion tons (10%), renewable energy 1.2 billion tons (10%), fuel switching 1.5 billion tons (12%) and CCS technology 2.6 billion tons (21%). Of Asia's CO₂ reduction of 6.8 billion tons in 2035, energy conservation will be responsible for 3.6 billion tons (53%), nuclear power 700 million tons (10%), renewable energy 600 million tons (9%), fuel switching 800 million tons (12%) and CCS 1.1 billion tons (16%). Thus, energy conservation, nuclear power, renewable energy, fuel switching and CCS will play a central role in realizing low-carbon energy sysytem.

[Major results] (China and India)

- **China**

China will shift from economic growth led by investments and exports to domestic consumption-led growth, and the Chinese GDP will grow at a rate of 5.6% per annum. China's primary energy consumption will expand at a rate of 2.4% per annum, from 1.77 Btoe in 2007 to 3.45 Btoe in 2035, accounting for 21% of the global total. In 2035, China will consume seven times as much energy as Japan and emit eight times as much CO₂ as Japan. It will be the largest energy consumer and CO₂ emitter in the world by 2035.

Oil: Oil demand will expand from 7.4 million b/d in 2007 to 18.8 million b/d in 2035 due to fast progress in motorization. As domestic oil production fails to increase, China's dependence on

imports for oil supply will rise from 48% in 2007 to 79% in 2035.

Coal: Chinese coal demand, mainly consumed in power generation, will increase from 1.29 Btoe in 2007 to 1.83 Btoe in 2035. Coal will remain the largest energy source, although its share of primary energy consumption will decline from 73% at present to 53%. Iron and steel production, which came to 490 million tons in 2007, will peak in the near future and decline to just under 400 million tons through 2035. As a result, industrial coal consumption will fall gradually.

Technologically advanced scenario: China's primary energy consumption will peak out in 2033 due to the introduction of advanced technology through technology transfers from developed countries. In 2035, energy savings of 800 million toe (or 23%) compared to the reference scenario will be achieved. Due to energy conservation efforts and the expanded introduction of nuclear power and other non-fossil energy, China's CO₂ emissions will peak out in 2030 if CCS is not considered and in 2025 if CCS is considered. In 2035, CO₂ will be reduced by 3.4 billion tons (or 35%) more than in the reference scenario if CCS is not considered (4.0 billion tons (or 41%) more if CCS is considered).

● India

The Indian economy will grow steadily at a rate of 6.1% per annum reflecting on an expanding labor population. India's primary energy consumption will increase at a rate of 3.7% per annum, faster than China, and will almost triple from 430 million toe in 2007 to 1.21 Btoe in 2035.

Oil: Oil demand will increase from 2.9 million b/d in 2007 to 7.0 million b/d in 2035. As a large increase in domestic oil production cannot be expected, India's dependence on imports for oil supply will rise sharply from 69% in 2007 to 86% in 2035.

Natural gas: Natural gas demand will grow at a high rate of 5.7% per annum, from 30 million toe in 2007 to 160 million toe in 2035.

Coal: Coal demand mainly used for electricity generation will grow at a rate of 3.4% per annum, more than double from 240 million toe in 2007 to 610 million toe in 2035. Coal will thus remain the largest energy supply source, accounting for 51% of primary energy consumption. As India's dependence on coal imports increases in the future, securing coal import sources will be a challenge amid growing coal demand in Asian countries.

Technologically advanced scenario: India's primary energy consumption in 2035 will be 300 million toe (or 25%) less than in the reference scenario, supported by the expanded introduction of advanced energy conservation technology. India's CO₂ emissions in the Technologically advanced scenario will peak out in 2034 if CCS is considered and will be 1.4 billion tons (or 42%) less than in the reference scenario in 2035.

[Implications]

- **Tackling climate change issues through technology transfers**

Given the rapid increase in CO₂ emissions in Asian developing countries, such as China and India, it is clear that reducing environmental burdens through international transfers of advanced energy conservation technology to these Asian countries will contribute to improving environmental problems in Asia, also from the viewpoint of cost effectiveness in Asia as a whole. It is important for Japan to cooperate toward achieving sustainable economic growth in Asian countries in an integrated manner, and at the same time contribute to grapple with global warming issues through transfers of sophisticated energy conservation technology to Asian countries.

- **Ensuring energy supply security**

In Asia, ensuring a stable energy supply will become an important issue as oil demand grows sharply and the dependence on imports for oil supply rises further in the future. To ensure a stable energy supply, the following point is important: to establish and strengthen emergency response systems as a countermeasure for short-term supply disruptions; to develop an international oil market that can respond flexibly to changes in supply and demand, enhance its functions and ensure transparency; to strengthen relations with oil-producing countries in the Middle East; and to implement domestic self-help measures in each country. On the other hand, excessive pursuit of self-interest by a single country could undermine the energy security of the entire region. As Asian countries share a mutual interest as major energy consuming nations, it is important that they deal with the issue as a problem concerning the entire region.

- **Challenges toward achieving the best energy mix**

Ensuring a stable supply of fossil fuels and their effective use

Fossil resources are ultimately finite, and their consumption is accompanied by greenhouse gas emissions. Nevertheless, when economic rationality, practicality and the lead time for the commercialization of innovative technology are considered, it is important to strive toward the effective utilization of fossil energy. In addition to ensuring a stable supply of fossil fuels, using them in a clean and highly efficient fashion is essential from the perspectives of energy security, environmental conservation.

[Oil] A substantial expansion in oil production cannot be expected in the Asian region, and its dependence on imports for oil supply will rise to 84% in 2035. Covering some 50% of Asia's oil consumption increase will be the Middle Eastern OPEC members that are rich with oil resources and more cost competitive than other oil-exporting countries. Steady investment in oil production capacity expansion to meet the rise in demand will be the key to the stability of the international oil market. On the demand side, an important issue will be to strive for the effective use of oil through the introduction of clean energy automobiles, whose full-fledged practical use is expected over the medium to long term.

[Natural gas] Natural gas production in the Asian region will peak while gas demand will increase due to fuel switching in the electricity generation and building sectors. Therefore, demand will expand for LNG and gas transported from Russia and central Asia via pipelines. As with oil, smooth investment toward the expansion of production and transportation capacity will be the key to the stabilization of natural gas demand and supply.

[Coal] Coal demand will increase for electricity generation due to its economic affordability and abundant resource endowment. In order to help prevent climate change, the development and introduction of high-efficiency coal-fired power generation and clean coal technology such as CCS are urgently required.

Nuclear power: Nuclear energy will play a major role in Asia, where ensuring energy security will become increasingly important due to fast-growing energy demand. Nuclear power, which is also important for helping to tackling global warming, should be increasingly introduced as a stable and core energy supply source.,

Technology development of renewable energy: Wind power and photovoltaic power generation are an important option among measures to prevent global warming. The introduction of biofuels is expected to improve automobiles' fuel efficiency and help reduce CO₂ emissions in the transportation sector. It is necessary to enhance systems for effective and efficient promotion of renewable energy diffusion and introduce innovation-supporting policies to further expand the use of renewable energy. It will also become important to consider the time frame with regard to technology development that contributes to ensuring energy security and enhancing measures against global warming. If we look to around 2020, progress in technology development and change in the energy supply and demand structure will be limited. However, since current technology development and supply-demand structural change are expected to bear fruit around 2030, technology strategies with a long-term outlook beyond 2030 are required.

[Conclusion]

In order to simultaneously achieve “3E objectives”—Energy (stable energy supply), Economy (economic development) and Environment (environmental conservation)—in Asia, regional countries should enhance their efforts to attain the best energy mix by diversifying energy supply sources and promoting a shift to low-carbon energy sources through energy conservation and fuel switching.

Japan, which has technological, economic and institutional advantages over other Asian countries, has a great role to play in this respect. In particular, Japan is competitive in energy-saving and environmental conservation technology that plays a central role in achieving the 3E objectives simultaneously. Further development and utilization of these energy-saving and environmental conservation technology should be a key option of Japan’s international energy strategy. In the

future, it will be important for Japan to utilize these excellent technologies to step up efforts to achieve the 3E objectives simultaneously and accomplish its sustainable economic growth as a leading technology-oriented nation.

[Position of this outlook]

This outlook represents an estimate based on theoretical and numerical integrity under certain assumptions. Given various uncertainties, estimated figures can be expected to change considerably. But we would be happy to see our outlook serve as a reference or base for predicting future energy supply and demand.
